

# **TEA2164S**

# SWITCH MODE POWER SUPPLY PRIMARY CIRCUIT

- POSITIVE AND NEGATIVE OUTPUT CUR-RENT UP TO 1.2A AND – 1.7A
- A TWO LEVEL COLLECTOR CURRENT LIMI-TATION
- COMPLETE TURN OFF AFTER LONG DURA-TION OVERLOADS
- UNDER AND OVER VOLTAGELOCK-OUT
- SOFT START BY PROGRESSIVE CURRENT LIMITATION
- DOUBLE PULSE SUPPRESSION
- BURST MODE OPERATION UNDER STAND-BY CONDITIONS

#### DESCRIPTION

In a master slave architecture, the TEA2164S control IC achieves the slave function. Primarily designed for TV receivers and monitors applications, this circuit provides an easy synchronization and smart solution for low power stand by operation.

Located at the primary side the TEA2164S control IC ensures :

- the power supply start-up
- the power supply control under stand-by conditions
- the process of the regulation signals sent by the master circuit located at the secondary side
- direct base drive of the bipolar switching transistor - the protection of the transistor and the power
- supply under abnormal conditions.

For more details, refer to application note AN409.

Note : For the best accuracy of VCM1 value the TEA2164S is marked as follows : TEA2164SL (low range) or TEA2164SH (high range).

#### I - FIELD OF APPLICATION

The TEA2164S control circuit has been designed primarily for discontinuous mode flyback built with a master-slave architecture, whatever the field of application.

But due to its capability to synchronize the transistor switching-off with an external signal (line flyback) and due to an adapted burst-mode operation for a low power stand-by operation, the TEA2164 offers a smart solution for monitors and TV sets applications.

Power supply main features :

- maximum output power 140W (transistor forced gain : 3.5)
- Muting Control STAGE P1 Remote Svnchronizatio Standby SCANNING Input DEVICE С 10 VOLTAGE REGULATOR Remote Standby 777 TEA5170 **TEA2164S** μP \_\_\_\_ Ь INFRA-RED пп RECEIVER 2164S-06.EPS P1 : Output voltage adjustment in normal mode 7777 Power primary ground P2 : Output voltage adjustment in standby Second ground (isolated from mains)

- stand-by mode output power ( $1W \le Psb \le 6W$ ; efficiency > 50%)
- operating frequency up to 50kHz
- power-switch : bipolar transistor

Adapted master-circuit :

Monitor applicationStandard TV application TEA5170  $\rightarrow$ 

TEA2028B  $\rightarrow$ 

- Digital TV application  $\rightarrow$  TEA5170

(TEA2028B, TEA2029C and TEA2128 are deflection processors with built-in PWM generator).

#### **II - GENERAL DESCRIPTION**

In a master slave architecture, the TEA2164SControl IC, located at the primary side of an off line power supply achieves the slave function; whereas the master circuit is located at the secondary side. The link between both circuits is realized by a small pulse transformer (Figure 4).

In the operation of the master-slave architecture, four majors cases must be considered :

- normal operating
- stand-by mode
- power supply start-up
- abnormal conditions : off load, short circuit, ...

#### II.1 - Normal Operating (master slave mode)

In this configuration, the master circuit generates a pulse width modulated signal issued from the monitoring of the output voltage which needs the best accuracy (in TV applications : the horizontal deflection stage supply voltage). The master circuit power supply can be supplied by another output.

Figure 4 : System Description Waveforms

The PWM signal are sent towards the primary side through small differentiating transformer. For the TEA2164S positive pulses are transistor switchingon commands; and negative pulses are transistor switching-off commands (Figure 5). In this configuration, only by synchronizing the master oscillator, the switching transistor may be synchronized with an external signal.

#### II.2 - Stand-by Mode

In this configuration the master circuit no longer sends PWM signals, the structure is not synchronized; and the TEA2164S operates in burst mode. The average power consumption at the secondary side may be very low  $1W \le P \le 6W$  (as it is consumed in TV set during stand by).

By action on the maximum duty cycle control, a primary loop maintains a semi-regulation of the output voltages. Voltage on feed-backis applied on Pin 9.

Burstperiod is externally programmed by capacitor C1.

Figure 5 : Master Slave Mode Waveforms

Figure 6 : Burst Mode Waveforms

#### II.3 - Power Supply Start-up

After the mains have been switched-on, the  $V_{CC}$  storage capacitor of the TEA2164S is charged through a high value resistor connected to the rectified high voltage.

When Vcc reaches  $V_{CC}$  start threshold (9V typ), the TEA2164 starts operating in burst mode. Since

available output power is low in burst mode the output power consumption must remain low before complete setting-up of output voltage.

In TV application it can be achieved by maintaining the TV in stand-by mode during start-up (Figure 7).

#### II.4 - Abnormal conditions : safety functions

#### **Overvoltage Protection**

When  $V_{CC}$  exceeds  $V_{CC}$  max, an internal flip-flop stops output conduction signals. The circuit will start again after the capacitor C1 discharge ; it means : after loss of synchronization or after  $V_{CC}$ stop crossing (Figure 8).

In flyback converters, this function protects the power supply against output voltage runaway.

#### Under Voltage Lock-out

The TEA2164S control circuit stops operating when  $V_{CC}$  goes under  $V_{CC}$  stop.

#### Power Limitation, Current Protection, Long Duration Overload Protection

- Output power limitation : by a pulse by pulse collector current limitation the TEA2164S limits the maximum output power. V<sub>CM1</sub> is the corresponding voltage threshold, its detection is memorized up to the next period.
- Current protection (transistor protection) Under particular conditions a hard overload or short circuit may induce a flux runaway in spite of the current limitation (V<sub>CM1</sub>).

The TEA2164S control circuit features a second

current protection,  $V_{CM2}$ . When this threshold is reached an internal flip-flop memorizes it and output conduction signals are inhibited. The circuit will send base drives again after capacitor C1 discharge (Figure 8).

- Long duration overload protection : (Figure 9) An overload is detected when the sense-voltage on Pin 11 reaches  $V_{CM3}$  before a negative pulse has been applied to Pin 6. In this case the capacitor C2 (connected to Pin 3) is charged with I<sub>3</sub> ch up to the end of the period and discharged with I<sub>3</sub> disch until a next  $V_{CM3}$  detector. By this way in case of long duration overload, the capacitor keeps charging at each period and its voltage encreases gradually. When the voltage on Pin 3 exceeds  $V_{C2}$ , the TEA2164S control circuit stops sending base drives and memorizes this event. No restart is allowed as long as  $V_{pin 3}$  is higher than  $V_{C2}$  and  $V_{CC}$  higher than 4.8V.

#### \* Remark :

- The harder is the overload the faster is the protection
- The capacitor keeps charging between two burst after  $V_{\text{CM2}}$  detection.

SGS-THOMSON MICROELECTRONICS

Figure 11 : Repetitive Over-current Protection

#### **III - SWITCHING OSCILLATOR AND SYNCHRONIZATION**

#### III.1. Switching oscillator

When the TEA2164S control circuit operates in burst mode, the switching frequency is fixed by the free frequency oscillator. The period is determined by two external components Co and Ro.

#### **III.2. Synchronization**

When the master-circuit starts to send pulses both oscillators are not synchonuous.

Figure 12 : Free Frequency Running

In order to avoid any erratic conduction of the power transistor, the first synchronization pulse will arrive simultanously with the sawtooth return of the TEA2164S oscillator.

To get synchronization the free frequency must be higher than the synchronization frequency.

2164S-15.EPS

#### III - SWITCHING OSCILLATOR AND SYNCHRONIZATION (continued)

Figure 13 : Synchronization Pulse Shaper and Synchronization

SGS-THOMSON MICROFLECTRONICS

#### **IV - MAXIMUM DUTY CYCLE LIMITATION**

Burst mode : The maximum duty cycle is controlled by the voltage on Pin 9 (Figure 15).

Synchronized mode : Normally the maximum duty cycle is set by the master circuit. However the maximum conducting time will never exceed the value given by the comparison of the oscillator wave-form with the 2.5V internal threshold.

#### **V - OUTPUT STAGE**

TEA2164S output stage has been designed to drive switching bipolar transistor.

- Each base drive begins with a positive pulse  $I_{BON}$  that realizes an efficient transistor turn-on.

Figure 15 : Maximum Duty Cycle Limitation

- After the starting pulse I<sub>BON</sub>, the base current is proportional to the collector current. The current gain is easily fixed by a resistor R<sub>B</sub> (Figure 16).
- A fast and safe transistor turn-off is realized by a fast positive base current cut-off and by applying a negative base drive which draws stored carriers. Atypical 0.7s delay prevents from cross-conduction of positive and negative output stages.

**Remark :** In order to reduce power dissipation on the positive output stage with the low gain transistors, for high base currents the positive output stage operates in saturated mode (Figure 17). This can be achieved by using a resistor between  $V_{CC}$  and  $V_{+}$ .

# V - OUTPUT STAGE (continued)

### **VI - MONITOR APPLICATIONS**

In most of monitor applications, the power supply must start-up under full load conditions and the stand -by mode is no longer useful.

The energy of the starting burst must be high enough to ensure start-up, then the capacitor C1 must be higher in these applications than on TV application (typ. :  $1\mu$ F).
